Bill splitter

Music player

Kanban board

Lovable Basics

Lovable is a tool that lets you build software products without writing any code. Whether you want to create a website, app, internal tool, or AI product - Lovable helps you do it visually and fast

Prompt

Lovable's prompt-based system makes app creation simple

-  Just **describe what you want to build** in the prompt box
-  The more specific you are, the better the results
-  **Start with clear and detailed prompts**
-  You can **refine and adjust your project as you go**

Example: *"Create a dashboard with user login, monthly sales in a line chart, and customer demographics in a pie chart."*

Templates

Lovable offers [templates](#) to help you get started quickly on popular project types, such as dashboards, e-commerce sites, or social apps, for a quick setup.

Once the template loads, **use prompts to adjust features, add new elements, or fine-tune the design to match your vision**

Lovable Hacks

Tips and Tricks (1/2)

Use buzzwords: They are a game changer and elevate your design instantly.

Iterate like a designer: The revert function is your best friend. Try bold variations. Don't fix broken foundations, instead, quickly revert and rebuild them.

Use this layout upgrade prompt: "Keep content the same, but improve spacing, visual hierarchy, and make it feel premium". It fixes 80% of design issues in one sentence.

If your first prompt isn't great, restart instantly: Don't waste time fixing a broken foundation.

Use images to make quick fixes: Take a screenshot of a bug, highlight the issue and drop a one-liner, "this spacing feels off, please make it tighter and cleaner."

Tips and Tricks (2/2)

Use real component libraries: When things look generic, don't force it. Drop in better building blocks from: 21s.dev, Acternity UI, HyperUI. Copy prompt and paste it into your Lovable project.

Add subtle motion to feel high-end: Prompt "Smooth hover transitions, fade-in on scroll, soft entrance animations". Or "Animate this logo on hover."

Edit visually to save time: You don't have to prompt everything. Select a specific element using visual edit, and then prompting it directly.

Make it mobile in one line: Prompt "Make this page responsive and optimized for mobile." Lovable gets 80% there - just preview both versions before shipping.

Final launch checklist: Before you ship, don't forget to (1) add title + description (SEO), (2) upload a favicon + OG/social image and, (3) connect your domain

Lovable Deepdive

Start with intention

Before opening Lovable, ask yourself: What am I building? Who is it for? What should the user do here? Your prompt is only as good as your clarity.

Build in blocks

Lovable works best when you prompt one section at a time. Don't write: "Build a landing page." Write: "Create a hero with a large headline, supporting text, and CTA." Then move to the next block. Think modular. You'll be faster, and stay in control.

Use real content

Placeholder copy won't bring you far. Even rough drafts are better than lorem ipsum. A real headline forces the right spacing. A real CTA reveals whether the layout makes sense. Design decisions should respond to the meaning.

Think in components

Cards, badges, buttons, modals, inputs, tooltips, toggles. Be specific. "Add a card with an avatar, name, and follow button" works better than "Add a user section." Build your UI like a system of parts.

Use buzzwords

Words like *“playful,” “premium,”* or *“cinematic”* do more than set the mood. They shape structure, color, depth, and motion. Add these into your prompt early to get more beautiful results.

“Minimalist, glassmorphic, floating elements”

“Bold, bright colors, rounded corners”

“Luxury, editorial, tactile”

Embed visuals by URL

You can embed Midjourney videos, animations, or even live demos directly into the layout. Just drop them in with URLs. But be specific. Where does it go? What does it support? Layout responds to media. Treat visuals as part of the flow, not decoration added later.

Use the visual edit function

The edit button will literally saves you hours! Don't re-prompt a full section just to update a button label or spacing. Just edit it. This makes iteration so much easier. It also helps keep layout stability, small changes stay scoped, and nothing gets accidentally overwritten.

Add Supabase early

Use Lovable for front-end, and Supabase for backend. It's the most powerful plugin out there. Add authentication, connect a CMS, let it just create some tables to store recurring information about your project.

Version history is your friend

Lovable autosaves, so you can work and think incrementally. Make one change at a time. Don't touch layout, copy, colors, and spacing in a single prompt. Clarity compounds.
